# Lecture 7 Regularized least-squares and Gauss-Newton method

- multi-objective least-squares
- regularized least-squares
- nonlinear least-squares
- Gauss-Newton method

# Multi-objective least-squares

in many problems we have two (or more) objectives

- we want  $J_1 = ||Ax y||^2$  small
- and also  $J_2 = ||Fx g||^2$  small

 $(x \in \mathbf{R}^n \text{ is the variable})$ 

- usually the objectives are competing
- we can make one smaller, at the expense of making the other larger

common example: F = I, g = 0; we want ||Ax - y|| small, with small x

### Plot of achievable objective pairs

plot  $(J_2, J_1)$  for every x:

note that  $x \in \mathbf{R}^n$ , but this plot is in  $\mathbf{R}^2$ ; point labeled  $x^{(1)}$  is really  $\left(J_2(x^{(1)}),J_1(x^{(1)})\right)$ 

- shaded area shows  $(J_2, J_1)$  achieved by some  $x \in \mathbf{R}^n$
- clear area shows  $(J_2,J_1)$  not achieved by any  $x \in \mathbf{R}^n$
- boundary of region is called *optimal trade-off curve*
- corresponding x are called *Pareto optimal* (for the two objectives  $||Ax y||^2$ ,  $||Fx g||^2$ )

three example choices of x:  $x^{(1)}$ ,  $x^{(2)}$ ,  $x^{(3)}$ 

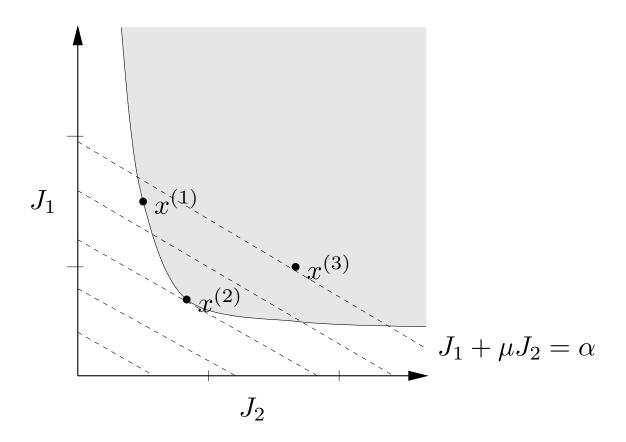

- $x^{(3)}$  is worse than  $x^{(2)}$  on both counts  $(J_2 \text{ and } J_1)$
- $x^{(1)}$  is better than  $x^{(2)}$  in  $J_2$ , but worse in  $J_1$

#### Weighted-sum objective

ullet to find Pareto optimal points, i.e., x's on optimal trade-off curve, we minimize weighted-sum objective

$$J_1 + \mu J_2 = ||Ax - y||^2 + \mu ||Fx - g||^2$$

- ullet parameter  $\mu \geq 0$  gives relative weight between  $J_1$  and  $J_2$
- ullet points where weighted sum is constant,  $J_1+\mu J_2=\alpha$ , correspond to line with slope  $-\mu$  on  $(J_2,J_1)$  plot

- $\bullet \ x^{(2)}$  minimizes weighted-sum objective for  $\mu$  shown
- ullet by varying  $\mu$  from 0 to  $+\infty$ , can sweep out entire optimal tradeoff curve

#### Minimizing weighted-sum objective

can express weighted-sum objective as ordinary least-squares objective:

$$||Ax - y||^2 + \mu ||Fx - g||^2 = \left\| \begin{bmatrix} A \\ \sqrt{\mu}F \end{bmatrix} x - \begin{bmatrix} y \\ \sqrt{\mu}g \end{bmatrix} \right\|^2$$
$$= \left\| \tilde{A}x - \tilde{y} \right\|^2$$

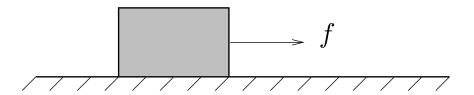

where

$$\tilde{A} = \begin{bmatrix} A \\ \sqrt{\mu}F \end{bmatrix}, \qquad \tilde{y} = \begin{bmatrix} y \\ \sqrt{\mu}g \end{bmatrix}$$

hence solution is (assuming  $ilde{A}$  full rank)

$$x = \left(\tilde{A}^T \tilde{A}\right)^{-1} \tilde{A}^T \tilde{y}$$
$$= \left(A^T A + \mu F^T F\right)^{-1} \left(A^T y + \mu F^T g\right)$$

#### **Example**

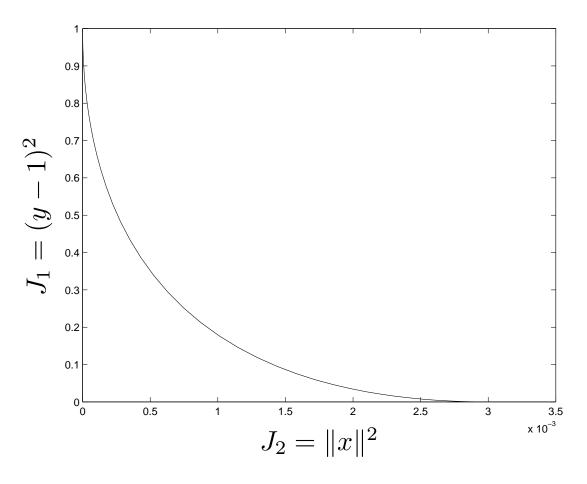

- unit mass at rest subject to forces  $x_i$  for  $i-1 < t \le i$ ,  $i=1,\ldots,10$
- $y \in \mathbf{R}$  is position at t = 10;  $y = a^T x$  where  $a \in \mathbf{R}^{10}$
- $J_1 = (y-1)^2$  (final position error squared)
- $J_2 = ||x||^2$  (sum of squares of forces)

weighted-sum objective:  $(a^Tx - 1)^2 + \mu ||x||^2$ 

optimal x:

$$x = \left(aa^T + \mu I\right)^{-1} a$$

optimal trade-off curve:

- ullet upper left corner of optimal trade-off curve corresponds to x=0
- bottom right corresponds to input that yields y = 1, i.e.,  $J_1 = 0$

### Regularized least-squares

when F = I, g = 0 the objectives are

$$J_1 = ||Ax - y||^2, J_2 = ||x||^2$$

minimizer of weighted-sum objective,

$$x = \left(A^T A + \mu I\right)^{-1} A^T y,$$

is called *regularized* least-squares (approximate) solution of  $Ax \approx y$ 

- also called *Tychonov regularization*
- for  $\mu > 0$ , works for any A (no restrictions on shape, rank . . . )

estimation/inversion application:

- Ax y is sensor residual
- prior information: x small
- or, model only accurate for x small
- ullet regularized solution trades off sensor fit, size of x

### Nonlinear least-squares

nonlinear least-squares (NLLS) problem: find  $x \in \mathbb{R}^n$  that minimizes

$$||r(x)||^2 = \sum_{i=1}^m r_i(x)^2,$$

where  $r: \mathbf{R}^n \to \mathbf{R}^m$ 

- r(x) is a vector of 'residuals'
- reduces to (linear) least-squares if r(x) = Ax y

### Position estimation from ranges

estimate position  $x \in \mathbb{R}^2$  from approximate distances to beacons at locations  $b_1, \ldots, b_m \in \mathbb{R}^2$  without linearizing

- we measure  $\rho_i = ||x b_i|| + v_i$  ( $v_i$  is range error, unknown but assumed small)
- NLLS estimate: choose  $\hat{x}$  to minimize

$$\sum_{i=1}^{m} r_i(x)^2 = \sum_{i=1}^{m} (\rho_i - ||x - b_i||)^2$$

#### Gauss-Newton method for NLLS

**NLLS:** find 
$$x \in \mathbb{R}^n$$
 that minimizes  $||r(x)||^2 = \sum_{i=1}^m r_i(x)^2$ , where  $r: \mathbb{R}^n \to \mathbb{R}^m$ 

- in general, very hard to solve exactly
- many good heuristics to compute locally optimal solution

#### **Gauss-Newton method:**

```
given starting guess for x repeat linearize r near current guess new guess is linear LS solution, using linearized r until convergence
```

#### Gauss-Newton method (more detail):

• linearize r near current iterate  $x^{(k)}$ :

$$r(x) \approx r(x^{(k)}) + Dr(x^{(k)})(x - x^{(k)})$$

where Dr is the Jacobian:  $(Dr)_{ij} = \partial r_i/\partial x_j$ 

write linearized approximation as

$$r(x^{(k)}) + Dr(x^{(k)})(x - x^{(k)}) = A^{(k)}x - b^{(k)}$$
$$A^{(k)} = Dr(x^{(k)}), \qquad b^{(k)} = Dr(x^{(k)})x^{(k)} - r(x^{(k)})$$

 $\bullet$  at kth iteration, we approximate NLLS problem by linear LS problem:

$$||r(x)||^2 \approx ||A^{(k)}x - b^{(k)}||^2$$

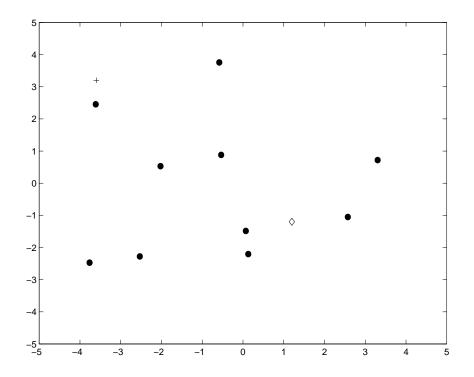

• next iterate solves this linearized LS problem:

$$x^{(k+1)} = \left(A^{(k)T}A^{(k)}\right)^{-1}A^{(k)T}b^{(k)}$$

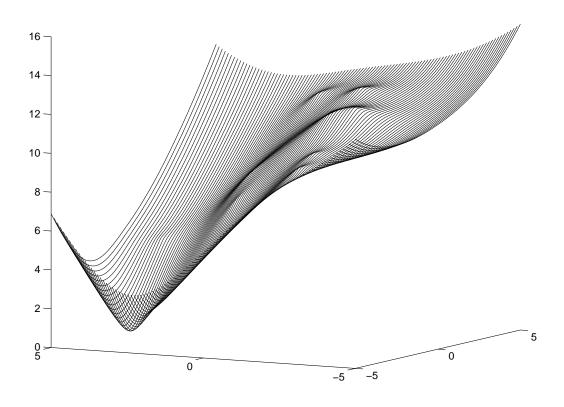

• repeat until convergence (which *isn't* guaranteed)

# **Gauss-Newton example**

- 10 beacons
- + true position (-3.6, 3.2);  $\diamondsuit$  initial guess (1.2, -1.2)
- ullet range estimates accurate to  $\pm 0.5$

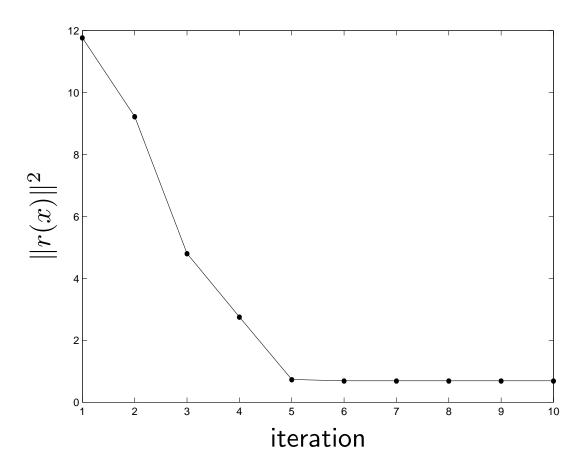

# NLLS objective $||r(x)||^2$ versus x:

- for a linear LS problem, objective would be nice quadratic 'bowl'
- ullet bumps in objective due to strong nonlinearity of r

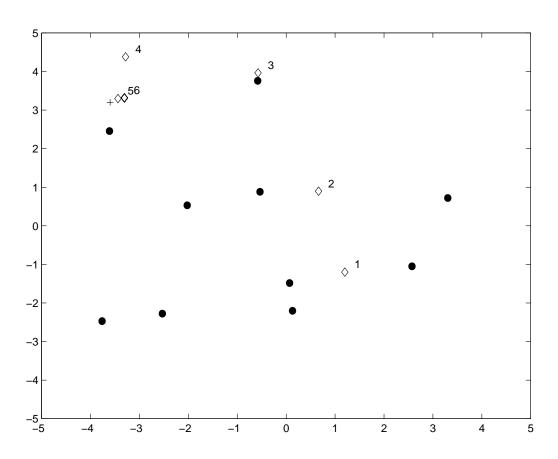

objective of Gauss-Newton iterates:

- $\bullet \ x^{(k)}$  converges to (in this case, global) minimum of  $\|r(x)\|^2$
- convergence takes only five or so steps

- final estimate is  $\hat{x} = (-3.3, 3.3)$
- estimation error is  $||\hat{x} x|| = 0.31$  (substantially smaller than range accuracy!)

### convergence of Gauss-Newton iterates:

useful varation on Gauss-Newton: add regularization term

$$||A^{(k)}x - b^{(k)}||^2 + \mu ||x - x^{(k)}||^2$$

so that next iterate is not too far from previous one (hence, linearized model still pretty accurate)
